Introduction

- heat stress \Rightarrow mRNA and microbiota
- heat stress \Rightarrow complex trait
- complex trait modeled as quantitative trait

Objective: The identification of mRNA, bacteria and their association with heat stress

Material and methods – phenotype

EBVs:

- rectal temperature
- drooling score
- respiratory score

MME:

$$y = \mathbf{XB} + \mathbf{Za} + \mathbf{Wp} + e$$

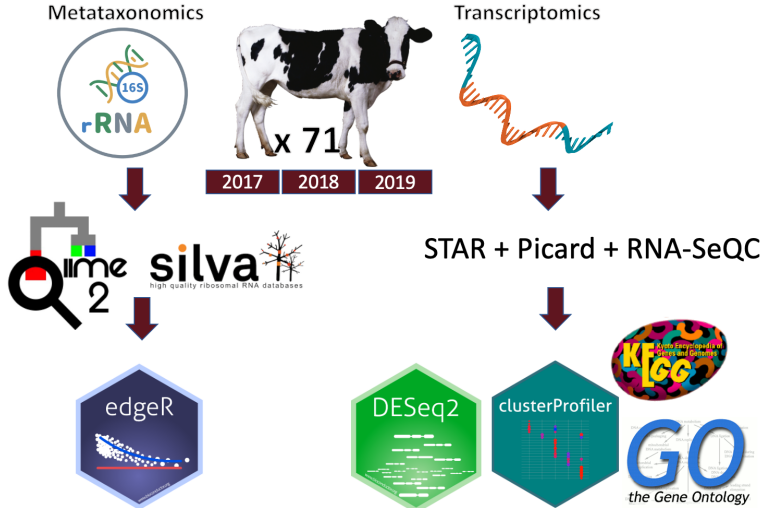

where: y – phenotype (RT, DS, RS);

B – fixed effects (farm-year, parity, lactation stage, milking stage, testing time, temperature-humidity index);

a – animal additive genetic effects;

p – permanent environmental effects; e – residual errors

Material and methods – workflow

Material and methods – integration analysis

1. Correlation analysis

2. Adjacency matrix

$$a_{mn} = |c_{mn}|^\beta$$

3. Topological overlap matrix (TOM)

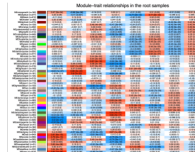

5. Eigengenes calculation for each module

4. Hierarchical clustering (dynamic tree)

6. Correlation analysis of eigengenes with phenotypes

Results – 16S rRNA

BIostatISTICS GROUP
WROCLAW, POLAND

232 unique genera

Results – mRNA

- 2,035 differentially expressed genes for rectal temperature
- 1,886 for drooling score
- 1,958 for respiratory score
- expression of around 80% differentially expressed genes was down-regulated

Results – GSEA (KEGG)

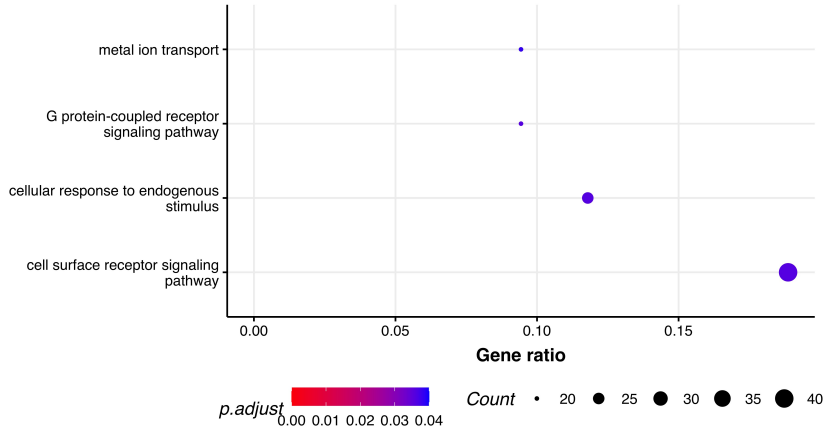

BIostatISTICS GROUP
WROCLAW, POLAND

Results – GSEA (GO)

BIostatISTICS GROUP
WROCLAW, POLAND

Results – WGCNA (hierarchical clustering)

BIostatISTICS GROUP
WROCLAW, POLAND

Cluster Dendrogram

Results – WGCNA (module-trait association)

BIostatISTICS GROUP
WROCLAW, POLAND

Conclusions

- most of the genera were significantly associated with rectal temperature
- heat stress causes the inhibition of growth of some microbial populations
- heat stress causes down-regulation of gene expression
- significantly associated microbiome-host transcriptome interaction
- hub genes/bacteria of significantly associated modules (*CSF3R*, *Lactococcus* and *Rhizobium*) showed the importance of multiomics integration in the analysis of complex traits
